A substance for lowering high cholesterol level in serum and a method for preparing the same

5 A high cholesterol level in serum can be lowered effectively by altering the intestinal metabolism of lipids. In this case the aim may be to hamper the absorption of triglycerides, cholesterol or bile acids. It has been observed in a number of investigations that certain plant sterols, such as  $\beta$ -sitosterol (24-ethyl-5-cholestene-3 $\beta$ -ol) and its hardened form,  $\beta$ -sitostanol (24-ethyl-5 $\alpha$ -cholestane-3 $\beta$ -ol), lower serum cholesterol levels by reducing the absorption of dietary cholesterol from the intestines (1-25). The use of plant sterols can be considered safe, since plant sterols are natural components of vegetable fats and oils. Plant sterols themselves are not absorbed from the intestines, or they are absorbed in very low concentrations. A decreased incidence of coronary disease is clearly associated with a decrease in serum cholesterol, in particular LDL cholesterol. A high serum cholesterol value is the most significant single indicator of the risk of coronary disease.

25 The degree of cholesterol absorption depends on a hereditary property, apoprotein E-phenotype. Apoprotein E is a protein which belongs to serum lipoproteins and takes part in the transport of cholesterol in the system (26). Of alleles associated with the synthesis of apoprotein E, i.e. the lipoprotein which affects absorption, there are known three types, e2, e3, and e4, which combine in pairs at random. Alleles are capable of forming in total six different combinations. The higher the sum of the subindices, the better absorbable the cholesterol and the higher the level of cholesterol, in particular bad LDL cholesterol, in the serum (27). e4 allele is overrepresented among the hereditary factors of Finns, so that its proportion is almost double as compared with many European populations (28).

Finns are indeed exceptionally sensitive to dietary flaws and to fatty and high-cholesterol food (29).

Serum cholesterol levels can be lowered by dietary means, by paying attention to the quantity and type of the fat ingested and to the amount of cholesterol intake. In practice, however, these means do not always lead to a satisfactory end result. Other methods, suitable for the entire population, for reaching serum cholesterol levels lower than the present ones must be searched for. Increasing the fiber content of food is a method of limited effect. The cholesterol-lowering effect of soluble fiber in food is based on the binding and removal of bile acids. Since the absorption of cholesterol is of fundamental significance in the regulation of the cholesterol level in serum, it is logical to aim at developing methods by which the absorption of cholesterol can be prevented or reduced.

Pollak demonstrated that ingested plant sterol lowered the level of serum cholesterol in man (1). The same had previously been observed in experimental animals (2, 3). It has been observed in a number of investigations that large doses of plant sterols lower the levels of serum cholesterol, at best by 10-20 % (4, 5). In these experiments, large amounts, up to 24 g/day, of  $\beta$ -sitosterol in crystalline form were used (6). In certain experiments the serum cholesterol level was lowered significantly even with lower doses (7), although a small amount of soluble sitosterol administered in the form of fatty acid esters did not seem to lower serum cholesterol very effectively (8). Sitosterol preparations have in general been well tolerated in long-term use (9).

Natural plant sterols resemble cholesterol in their structure. The differences between a cholesterol molecule and a plant sterol molecule are primarily found in the structure of the side chain of the basic frame. An ordinary diet

contains plant sterols 100 - 300 mg/day. Most of the plant sterol in the diet is  $\beta$ -sitosterol, and approx. one-third is campesterol. Small amounts of saturated  $5\alpha$ -sitostanols are also present in food. Usually the campesterol concentrations in serum in particular reflect the degree of absorption of cholesterol (10, 11, 12). Variation in the amounts of plant sterols in the diet affects the serum cholesterol level, but this is an area which has not been studied much. Plant sterols are poorly absorbed from the intestines. Plant sterols which are scantily absorbed into the system (less than 10 % of the sterols) (30, 31, 32) are excreted in the bile and through that in the stools. At present it is easy to measure sterol levels from food, serum or stool samples by gas chromatographic methods. The levels in serum are in part dependent on the plant sterol amounts derived from the diet and in part on the efficiency of the absorption of sterols. In general the plant sterol levels in serum remain below 1/300 of the serum cholesterol level, since the absorbed plant sterol fraction is excreted from the system in the bile.

Even large ingested doses of plant sterols do not show in serum plant sterol levels. The values remain at the normal level, since in man the plant sterol absorption capacity is rapidly saturated. The serum plant sterol level rises to a detrimental level in a few rare diseases such as cerebrotendinotic xanthomatosis and sitosterolemia (33, 34, 35), in connection with which coronary disease is common. The incidence of these diseases is at maximum a few cases in a population of one million. Not a single case of these diseases has been observed in Finland. High plant sterol values are at times observed in patients suffering from certain hepatic diseases (36).

Studies of the metabolism of cholesterol have shown that sitosterol inhibits the absorption of both endogenic and dietary cholesterol from the intestines (13, 14). As a

result of this, the excretion of neutral steroids in the stools increases, which leads to a shortage of cholesterol in the liver and through that to a decreased serum cholesterol level. On the other hand, sitosterol does not affect the absorption of bile acids (13).

On the basis of experiments on animals, it seems that the action of sitosterol is based on its ability to displace dietary cholesterol in bile acid micelli (15, 16, 17). Similar results have also been obtained in man (37). Various plant sterols have been demonstrated to affect in different ways the absorption of cholesterol (19, 38). Previous studies carried out on experimental animals give the impression that sitostanol is the most effective inhibitor of cholesterol absorption (38) and is itself almost non-absorbable. Furthermore, an uncontrolled study on six subjects showed that free sitostanol (1.5 g/day) lowered the serum cholesterol (mainly LDL cholesterol) in four weeks by as much as 15 %. During a pause of two weeks, the cholesterol values returned to the previous levels (20). Most plant sterol preparations contain a number of different plant sterols. The effect of a plant sterol mixture on the absorption of cholesterol varies, as does their own absorption (21, 22, 23).

The studies carried out so far have mainly concentrated on investigating how the form (crystalline, suspension, granular) in which plant sterols are dosed affects their efficacy in lowering serum cholesterol levels. Crystalline plant sterols do not to a significant degree dissolve in the micelli phase in the alimentary canal, and are therefore not capable of efficiently inhibiting cholesterol absorption. Oils and fats are only to a limited degree capable of dissolving free sterols. Only in a dissolved form do sterols inhibit the absorption of cholesterol. According to Heinemann and coworkers (24), sitostanol inhibited in an infusion experiment the absorption of cholesterol 82 %,

whereas sitosterol respectively inhibited the absorption 50 %.

In certain studies, fatty acid esters of sitosterol, such as sitosterol acetate or oleate or stigmasterol oleate dissolved in fat, have been used. In experiments on rats an "oil" of this type, having a sterol concentration up to 8 %, reduced the absorption of cholesterol by 20-40 % (22). During a high-cholesterol diet (500 mg/day), sitosterol oleate (2 g/day) dissolved in fat decreased the absorption of cholesterol in the test subjects on average by 33 % (25). In the same study, sitosterol mixed with food and in a lower dose (1 g/day) decreased the absorption of cholesterol by 42 %.

A German patent (Deutsches Patentamt, Offenlegungsschrift 2035069/January 28, 1971) relates to the adding of plant sterol fatty acid esters to cooking oil with the objective of lowering the serum cholesterol levels in man. The said patent proposes for use in the esterification of free sterols a method which in no case fulfills the requirements for the preparation of a food-grade product. According to the patent, the esterification is carried out between a free sterol and a fatty acid anhydride, with perchloric acid acting as a catalyst. The catalyst and reagent used cannot be accepted in a food process. In addition, the said patent relates to the fatty acid esters of only native plant sterols.

Many reagents which cannot be accepted as a food or for the production of a product intended as an additive for foods have been used in the preparation of sterol fatty acid esters. The use of, for example, chlorine (39), bromine (40), thionyl chloride (41) or anhydride derivatives of fatty acids is common. Of the methods previously patented, only the method of Baltes (Deutsches Patentamt, Offenlegungsschrift 2248921/April 11, 1974) for the esteri-

5      fication of sterols present in oils and fats by a chemical  
interesterification technique fulfills the criteria of food  
processes. In the said patent, free sterol and an excess of  
fatty acid esters are added to a mixture of oil or fat,  
whereafter the entire fatty mixture is interesterified by a  
commonly known interesterification technique.

10      The invention according to the present invention relates to  
the use of a sterol of an entirely different type for low-  
ering the cholesterol level in serum. What is involved is  
fatty acid esters of  $5\alpha$ -saturated sterols, especially sito-  
stanol fatty acid esters (sitostanol = 24-ethyl- $5\alpha$ -choles-  
tane- $3\beta$ -ol), which have been observed to lower cholesterol  
15      levels in serum with particular efficacy. The said esters  
can be prepared or used as such, or they can be added to  
foods, especially to the fatty part of a food. The sito-  
stanol fatty acid ester mixture is prepared by hardening a  
commercial  $\beta$ -sitosterol mixture (sitosterol = 24-ethyl-5-  
cholestene- $3\beta$ -ol).  $\beta$ -sitostanol can be prepared by a prior-  
20      known cholesterol hardening technique by hardening  $\beta$ -sito-  
sterol by means of a Pd/C catalyst in an organic solvent  
(43). This mixture has the approval of the FDA (Cytellin,  
Eli Lilly). A hardening degree of over 99 % is achieved in  
the reaction. The catalyst used in the hardening is removed  
25      by means of a membrane filter, and the obtained sitostanol  
is crystallized, washed and dried. In accordance with the  
invention, the  $\beta$ -sitostanol mixture, which contains campe-  
stanol approx. 6 %, is esterified with different fatty acid  
ester mixtures by a commonly known chemical interesterific-  
30      ation technique (44, 45, 46). A methyl ester mixture of the  
fatty acids of any vegetable oil can be used in the reacti-  
on. One example is a mixture of rapeseed oil and methyl  
ester, but any fatty acids which contain approx. 2-22 car-  
bon atoms are usable. The method according to the invention  
35      for the preparation of stanol fatty acid esters deviates  
advantageously from the previously patented methods in that  
no substances other than free stanol, a fatty acid ester or

a fatty acid ester mixture, and a catalyst are used in the esterification reaction. The catalyst used may be any known interesterification catalyst, such as Na-ethylate.

5 It is also to be noted that in the method used in our application, contrary to the method of Baltes, referred to above, the fat itself is not interesterified. In this case the fatty part of a fat preparation or some other food will retain its natural properties. It should be noted further  
10 that the interesterified mixture can be added directly to fat-containing foods or be used as such. Since the stanol part of the mixture is non-absorbable, the energy content of the stanol fatty acid ester mixture is only 20-40 % of the energy content of a conventional oil or fat, depending  
15 on the fatty acid composition. Thus the mixtures can be used advantageously also as substances decreasing the energy content of a food.

The action of  $\beta$ -sitostanol fatty acid esters on cholesterol  
20 absorption and on serum cholesterol levels has not been studied previously. The study on which this application is based investigated how plant sterol concentrations in serum were affected by sitostanol (composition:  $\beta$ -sitostanol 94 % and campestanol 6 %), a hardened form of sitosterol, dis-  
25 solved in rapeseed oil, both a) free and b) in the form of a fatty acid ester. The test arrangement of the study is shown in Diagram 1 in Appendix 1. The first step for all groups was a rapeseed oil intervention (50 g/d), for the control group a rapeseed oil intervention for the duration  
30 of the test, and for the other groups a compound according to the test arrangement scheme, added to rapeseed oil.

Table 1 in Appendix 2 shows that an increase in the  $\beta$ -sitostanol concentration of food lowered the concentrations  
35 of both  $\beta$ -sitosterol and campesterol in serum, but did not produce a clear change in the serum  $\beta$ -sitostanol concentrations. The results also show that an intake of  $\beta$ -sitostanol

in a soluble form - i.e. in the form of fatty acid esters - reduced the absorption of plant sterols more effectively than did free  $\beta$ -sitostanol taken in the same dosage. With respect to fatty acid esters of  $\beta$ -sitostanols there is additionally observed a clear dose response. It is evident that  $\beta$ -sitostanol also inhibits the absorption of  $\beta$ -sitosterol and campesterol, which can be seen as a decrease in their concentrations.

Respectively, the changes caused by stanol additions in the total and LDL serum cholesterol concentrations and in cholesterol absorption were also measured. The control group consumed ordinary rapeseed oil without stanol additions. Table 2 in Appendix 3 shows that cholesterol absorption was effectively reduced by a  $\beta$ -sitostanol fatty acid ester mixture (27.4 %) even if the stanol intake was relatively low, 895 mg/day. The cholesterol absorption of the control group did not change. The action of free  $\beta$ -sitostanol and a  $\beta$ -sitostanol fatty acid ester mixture on the cholesterol concentration in serum, as compared with the control group, is seen in Table 3 in Appendix 4. A  $\beta$ -sitostanol fatty acid ester mixture decreased both total cholesterol and LDL cholesterol more effectively than did free and  $\beta$ -sitostanol. A  $\beta$ -sitostanol fatty acid ester mixture dissolved in rapeseed oil (3.2 g of  $\beta$ -sitostanol/day) decreased total cholesterol by 9.5 % more and LDL cholesterol by 11.6 % more than did rapeseed oil alone. Respectively, the HDL/LDL cholesterol ratio rose significantly, from 0.32 to 0.52.

The studies carried out show clearly that by the addition of  $\beta$ -sitostanol fatty acid esters to, for example, food fats, significant advantages can be achieved both in the national nutrition and in the treatment of hypercholesterolemia, since 1) the mixture lowers cholesterol values in serum, 2) the mixture does not increase serum plant sterol concentrations, 3) the mixture can be used daily as a fat substitute in cooking normal food, even in large

doses (0.2 - 20 g/d), whereby the intake of energy from fat decreases.

Lipid changes caused by  $\beta$ -stanol fatty acid esters, observed in the study, are to be considered highly significant from the viewpoint of health. The significance of the results is emphasized by the possibility of using the compound alongside food preparations as part of ordinary cooking and an ordinary diet. Research results show that during an intervention diet the stanol level in serum does not rise, and that the levels of other plant sterols in the serum decrease. Thus the said  $\beta$ -stanol ester mixture is safe also for those few individuals who readily absorb all sterols or who have disturbances in sterol excretion. Furthermore, daily fat substitution decreases an individual's energy supply, since the effective stanol compound is not absorbed, i.e. it acts as a non-energy producing part of fat. There is no evidence of the said  $\beta$ -stanol ester mixture hampering the absorption of lipid-soluble vitamins or the vitamin levels in serum.

The uses of a sitostanol fatty acid ester mixture as a part of various fats and oils in fat-containing products are wide, since the physical properties of the mixture can be modified easily by altering the fatty acid composition of the mixture. In addition to this, the fatty acid composition of the  $\beta$ -stanol fatty acid ester mixture can be selected so as to contain large amounts of monoenes and polyenes, whereby its efficacy in lowering the cholesterol levels in serum are enhanced.

Since the  $\beta$ -sitostanol fatty acid ester mixture is prepared using raw materials belonging to normal food and production processes generally used in the food industry, there are no obstacles to the production and use of the compound.

Example 1

A  $\beta$ -sitostanol ester mixture was prepared on a pilot scale. 6 kg of  $\beta$ -sitostanol which had been dried overnight at 60 °C was esterified with 8.6 kg of a rapeseed oil methyl ester mixture. The esterification was carried out as follows:

A mixture of  $\beta$ -sitostanol and rapeseed oil fatty acid methyl ester was heated in a reaction vessel at 90-120 °C and under a vacuum of 5-15 mmHg. The drying was continued for an hour, 12 g of Na ethylate was added, and the reaction was continued for approx. 2 hours. The catalyst was destroyed by adding water to the mixture. After phase separation, the oil phase was dried under a vacuum.

A conversion of 98 % was achieved in the reaction. The obtained ester mixture can be used as such as an additive in fats.

Instead of a mixture of rapeseed oil fatty acid esters it is possible to use in the reaction a methyl ester or a methyl ester mixture of the fatty acids of any vegetable oil, especially of fatty acids which contain approximately 2-22 carbon atoms.

Example 2

Before the steam blowing of rapeseed oil,  $\beta$ -sitostanol ester mixture prepared in Example 1 was added, at 3, 6, and 13 % by weight, to the rapeseed oil. Mayonnaises containing the said fat mixtures at 65 % were prepared.

Mayonnaise:

%

fat mixture	65.0
thickening agent	2.0
salt	1.0
sugar	3.0
vinegar (10 wt.%)	3.0

11

mustard	2.0
water	24.0
total	100.0

5 The mayonnaise was prepared by homogenization by a known manner using a Koruma homogenizer.

There were no problems in the preparation of the mayonnaises, and their properties tested by sense perception did not differ from those of conventional mayonnaises.

10

### Example 3

Before the steam blowing of oil,  $\beta$ -sitostanol ester mixture prepared in Example 1 was added, at 3 and 6 % by weight, to the rapeseed oil.

15

The rapeseed oil to which the ester mixtures had been added remained clear at room temperature, and no permanent turbidity was observed in it when it was stored at refrigerator temperatures.

20

### Example 4

Other oils, such as sunflower, soybean, olive and corn oil, can also be used as the oil in the products according to Examples 2 and 3.

25

### Example 5

$\beta$ -sitostanol ester mixture prepared in Example 1 was added, at 10 and 20 % by weight, to the fatty part of a conventional soft margarine (composition: partly hardened soybean oil 35 %, coconut oil 5 %, rapeseed oil 60 %) before the steam blowing of the fat mixture.

30

The DP (dropping point) and NMR values of the mixtures were analyzed

35

1) the mixture as such

- 2) the mixture + ester mixture at 10 %
- 3) the mixture + ester mixture at 20 %

5	Mixture	DP (°C)	NMR values (%)				
			10°C	20°C	30°C	35°C	40°C 45°C
	1)	31.9	24.2	11.6	2.7	0.7	0.0 0.0
	2)	30.4	21.4	10.0	1.8	0.2	0.0 0.0
	3)	29.6	25.4	9.2	2.0	0.6	0.0 0.0

- 10 A margarine which contained fat 80 % was prepared by a generally known method. The physical and sense perceivable properties of the margarine corresponded to those of conventional margarines.

Claims

1. A substance lowering cholesterol levels in serum, characterized in that it comprises a  $\beta$ -sitostanol fatty acid ester or a  $\beta$ -sitostanol fatty acid ester mixture.
- 5 2. A substance according to Claim 1, characterized in that the fatty acids of the mixture contain 2-22 carbon atoms.
- 10 3. A substance according to any of Claims 1-2, characterized in that it has been brought to a form soluble in fats by esterifying free  $\beta$ -sitostanol with a fatty acid ester or a fatty acid ester mixture.
- 15 4. A substance according to any of Claims 1-3, characterized in that the substance is added to fat preparations or other foods.
- 20 5. A substance according to any of Claims 1-3, characterized in that it is used as an essential fat component or a fat substitute.
- 25 6. A substance according to Claim 5, characterized in that it is used in cooking oils, margarines, butter, mayonnaise, salad dressings, shortenings, etc.
- 30 7. A substance according to any of Claims 1-3, characterized in that it can be consumed as such, as part of the diet.
- 35 8. A process for the preparation of the substance according to Claim 1, characterized in that free  $\beta$ -sitostanol is esterified with a fatty acid ester or a fatty acid ester mixture in the presence of an interesterification catalyst.
9. A process according to Claim 8, characterized in that the reaction is carried out at a temperature of approx. 90 - 120 °C and under a vacuum of approx. 5 - 15 mmHg.
